Threat-Based Land Management in the Northern Great Basin: A Field Guide

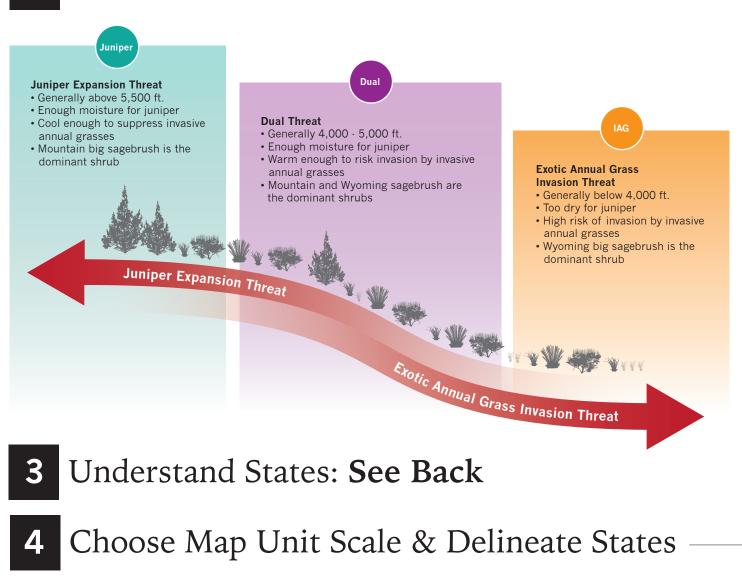

Before Using this Guide You Should Know

Sagebrush ecosystems in the Northern Great Basin face existential threats from invasive

With this method, users map simplified ecological states and estimate future trend. Broad ranges of vegetation and environmental conditions can be mapped with the same state if faced with similar threats. Understanding plant communities and tracking true change over time requires detailed and repeated monitoring.

Understanding Threats

Now it's time to delineate states. Use the back of this guide to determine states and the examples in this panel to help decide at which scale to map. The appropriate scale for mapping states depends on your management objectives - there is no perfect answer. Map units should be small enough to feasibly manage, and large enough for management to matter in meeting objectives.

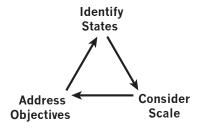

A Tale of Two Pastures: An Example Comparing Management and Mapping

Pasture 1 Objective: Manage pasture for maximum forage yield by containing juniper and aggressively controlling annual grasses. Maintaining sagebrush cover is a secondary priority to improving forage.

Juniper

Pasture 1: Only the densest stand of juniper

Pasture 2 Objective: Improve pasture for sage-grouse habitat by removing encroaching iuniper and maintaining sagebrush cover.

Mapping is an iterative process. Consider objectives, site and scale collectively. Use remote sensing to estimate map units and dedicate field time to important or ambiguous units.

is mapped as State C-Dual because diffuse juniper are not currently impacting forage quality. Pasture 2: A much larger State C-Dual

unit is mapped to include all diffuse juniper, as any juniper is a problem for sage-grouse.

Invasive **Annual Grasses**

Pasture 1: Small stands of State D-IAG are mapped within a State A matrix. The high-priority placed on controlling annuals justifies the time and effort to map small units.

annual grasses and expanding conifers. Land managers need to work at large spatial scales to address these two ecological threats, but have limited resources to do so.

This guide provides a framework for land managers to efficiently identify, discuss and address landscape-level threats. This guide is a decision-support system. It is not an instruction manual.

This decision-support system directly supports management objectives. Establishing your objectives is the first step to using this guide.

Steps for State Classification and Management

Establish your management objectives: Do this before using this guide, all other steps follow from your objectives. Clearly stated objectives will help you make key scale and management decisions.

Management objectives specify the overall desired outcome achieved by addressing a threat. The Bureau of Land Management provides a good resource to begin writing management objectives - a QR link is at the bottom right of this guide.

Understand threats and states: Environmental factors drive juniper encroachment and annual grass invasion. The resistance and resilience of a site will change how threats are expressed.

1 Relevant Ecology

Understand states: Use the decision tree, photographs, and illustrations on the back of this guide to understand and differentiate states. Recognize that reality will be more complex than the detail used in this framework.

Choose the appropriate scale and delineate states: Mapping is difficult and subjective. The size of an individual map unit depends on the total scale of your specific landscape and on your management objectives. Choose map units that are large enough to matter, but small enough to manage. There is no perfect answer.

Determine apparent trend: Assess the apparent trend of each state as upward, downward, stable or unclear. Consider all factors together. Apparent trend is a snapshot estimate of how the plant community may change in the future.

Identify management actions: Assign management actions to each state based on its apparent trend. Be sure to describe how management actions will achieve management objectives.

Using functional groups improves monitoring efficiency, reduces observer error and eases sampling timing. Functional groups make visually evaluating vegetation state and apparent trend feasible over large areas. We include seven functional groups in our models based on southeastern Oregon, but these groupings may vary across the range of this vast biome.

Large Perennial Bunchgrasses (LPBG) are the glue that holds the western sagebrush steppe together. LPBG root masses bind soil in place, effectively compete with annual grasses and provide forage and habitat for wildlife. Key species include bluebunch wheatgrass, Idaho fescue, needlegrasses and squirreltail.

Annual Forbs (AF) are generally

small-statured plants with highly variable productivity depending on year and site conditions. Common species include blue-eyed Mary (Collinsia sp.) and alyssum (Alyssum sp.). Large amounts of AF, especially of introduced species can indicate a depleted understory. This category does not include weeds such as yellow star-thistle which should be mapped and managed on a species-specific basis.

(SPBG) primarily refers to Sandberg's bluegrass, a low-state ured and early-growing species common across the western sagebrush steppe. SPBG can dominate in harsh, shallow soil sites or where heavy continuous grazing has reduced other bunchgrasses. Despite often occurring at high densities, SPBG have shallow root systems and do not compete as effectively with annual grasses.

Small Perennial Bunchgrasses

Perennial Forbs (PF) are a large, diverse and variable group and are important for wildlife habitat and forage. The aster family, as well as lupines and paintbrushes are particularly abundant.

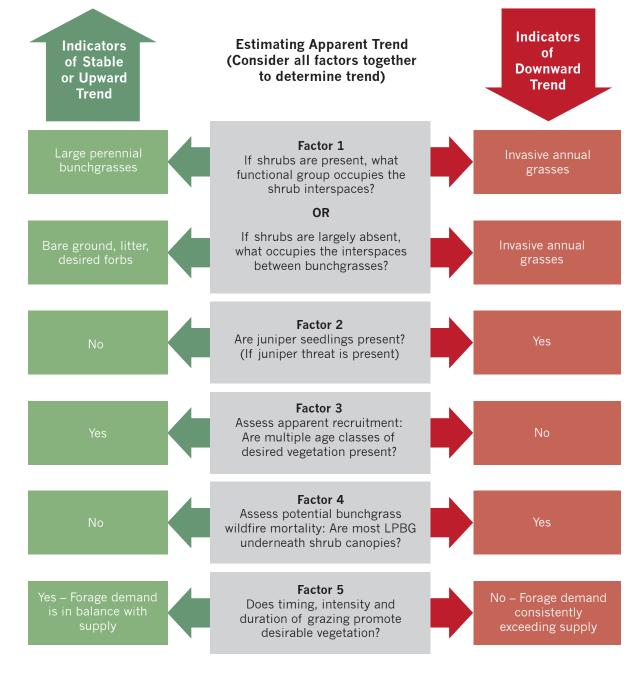

Determine Apparent Trend 5

Use these factors collectively to determine the apparent trend of a site. Apparent trend will help you determine what monitoring or actions are needed, if any. Decide if the trend is Upward, Stable, Downward, or Unclear. Unclear trends will likely require addition monitoring.

6 Management Actions

Select and prioritize management actions for each site based on the state, apparent trend, and management objectives. The example below shows how a user might manage for increasing the resistance and resilience of a site.

D

Pasture 2: As in the other pasture there are small annual grass patches, but they are included together in a larger State C-IAG because sage-grouse can tolerate small areas of annual grasses if most of the habitat is otherwise suitable.

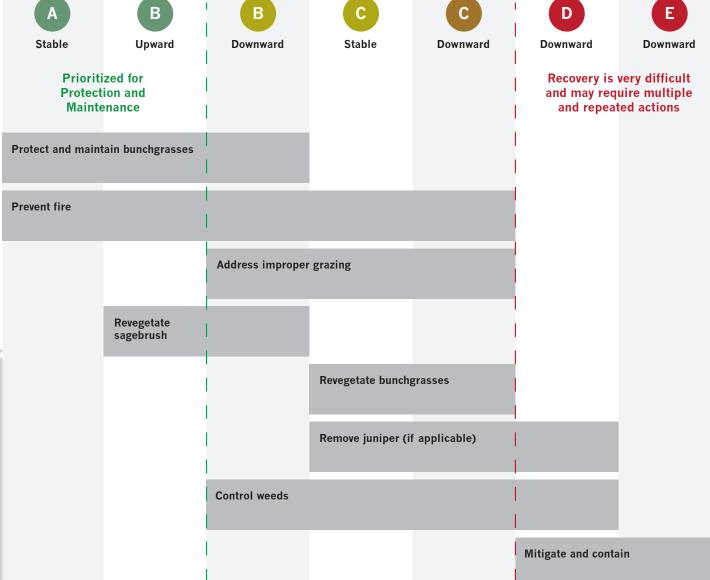

Invasive Annual Grasses (IAG), including cheatgrass, medusahead and ventenata, are species that can fundamentally alter vegetation communities by replacing native grasses, dramatically increasing fire frequency and leading to a loss of sagebrush and perennial cover.

Conifers include tree species that are encroaching on historically treeless sagebrush steppe. This guide primarily refers to juniper because Western juniper is of major concern in the northern portion of the sagebrush steppe, but Utah juniper and pinyon pine are major threats in other regions. Sagebrush includes several species and subspecies. Two subspecies of big sagebrush are the most abundant · Wyoming and mountain. Identifying subspecies of sagebrush can help understand site potential. resilience and restoration practices. Other shrub species can help identify past land use history and site potential. For example, a high proportion of rabbitbrush may indicate past disturbance, or greasewood may indicate saline soil conditions.

This is only an example. After using this guide to understand and assess threats, use in-depth resources and knowledgeable colleagues to select and prioritize management actions. Follow these OR Links to related land-management resources from the Bureau of Land Management and The Natural Resource Conservation Service.
