Conserving a Network of Climate-Resilient Lands

By Eric Aldrich

The Resilient and Connected Network, an ambitious GIS mapping tool developed over the past 10 years by more than 270 scientists led by The Nature Conservancy (TNC), gives conservationists a way to save biodiversity for the future. It is now available for land trusts, government agencies, and scientists for conservation planning throughout the contiguous lower 48 US states.

The Loess Hills of western Iowa, with its peak and saddle topography, is one of the places in the region that is most resilient to climate change. (© Mark Godfrey/TNC)

As the climate warms, species are moving to find more hospitable places to live. On average, each decade, species travel to areas that are 11 miles north and at an elevation that is 36 feet higher. On this map, the movement of mammals is shown in pink, birds in blue, and amphibians in yellow. (© Dan Majka and Nicholas Rapp/TNC)
How can conservationists continue to protect biodiversity if the cast of plant and animal species keeps moving to escape growing climate impacts?

Natural Neighborhoods and Highways
The answer, according to Dr. Mark Anderson, is to focus on the future. Anderson is director of science for TNC’s Eastern US Division and, for many years, has been studying the connections between climate change and shifting biodiversity. Anderson is also a GIS junkie who knows well the crucial role that GIS plays for land trusts, state agencies, and other entities planning conservation projects. Conservationists have limited funding and face huge challenges in their work preserving biodiversity and clean water and protecting the health of landscapes. They need GIS to help identify and focus on high-priority projects.

Rich data from scientists, universities, and state and federal agencies provides great insight into current biodiversity, habitat, and other natural features. But Anderson sought to see how GIS could identify places that would have long-term resilience as the climate changes.

Anderson and his team found that landscapes with diverse physical characteristics—such as steep slopes, tall mountains, deep ravines, and diverse soil types—create numerous microclimates that offer plants and animals the opportunity to move around their local neighborhood to find suitable

GIS has long been one of conservationists’ main go-to tools to identify and protect land, water, plants, fish, wildlife, and habitat across the globe. Using GIS to identify places with high levels of biodiversity has often played a leading role in those efforts.

Now, climate change is altering biodiversity and habitats. As warmer temperatures, increased flooding, and other climate impacts alter and destroy habitat, species are being forced to find new places to live. Diverse plants and animals that thrive in one landscape today may end up living in a very different landscape in the future.

Scientists have found that globally, species are moving an average of 11 miles north and 36 feet higher in elevation each decade to find more hospitable places to live.
Among the things that make places resilient to climate change are diverse physical characteristics—such as steep slopes, tall mountains, deep ravines, diverse soil types that create numerous microclimates and allow plants and animals to move to suitable habitat. The landscapes also have good connectivity, allowing movement across local microclimates and between climate-resilient landscapes.

In the area near Oklahoma’s Canadian River, prairies and contrasting wooded canyons provide climate-resilient habitat for plants and wildlife. (© Jay Pruett/TNC)

Using Esri’s advanced spatial analysis and modeling tools and working many long nights over the past 10 years, TNC scientists Clark, Arlene Olivero Sheldon, and Analie Barnett developed, tested, and retested methods to map and measure characteristics of resilient lands. Their analytical and problem-solving skills, coupled with their determination and passion for conservation, took the idea of a network of resilient lands from concept to reality.

One of the big challenges, according to Anderson, was persisting over the 10-year life-span of the project. During that time, the project grew organically region by region, starting with the Northeast. To ensure accuracy as the map was being built, the team had reviews by some 270 scientists, who
The Cumberland Forests area, which spans 253,000 acres across Tennessee, Kentucky, and Virginia, that not only safeguards wildlife habitat but also stores millions of tons of carbon.

Wisconsin’s Kettle Moraine region, which was shaped by glaciers during the last ice age and contains diverse features such as large kettle lakes and 300-foot-high ridges.

Bobcat Alley, a 32,000-acre forested corridor in northwestern New Jersey that provides habitat to state-endangered bobcats.

Along with providing safe places where species can thrive, the network of resilient lands also brings benefits to people. The lands mapped in the eastern US, for example, contain 75 percent of the region’s sources of drinking water, generate billions of dollars in outdoor recreation, store 3.9 billion tons of carbon, and mitigate 1.3 million tons of pollution. Taken together, this results in an estimated $913 million in avoided health-care costs.

“...To achieve conservation at the scale needed, we must collaborate with people and organizations across both the public and private sectors,” Anderson said. “Keeping these resilient areas safe and healthy will require a wide range of conservation practices including such things as sustainable management, public and private land acquisition, and easements.”

Numerous state and federal agencies and land trusts have already incorporated the map’s data into their conservation planning. Among the growing number of state agencies incorporating the map into their state Wildlife Action Plans are Connecticut, Massachusetts, New Hampshire, New York, and South Carolina.

The urgency of protecting lands and biodiversity given the challenges of climate change is clear and pressing, according to Andrew Bowman, president of the Land Trust Alliance. At Rally 2019: The National Land Conservation Conference, the country’s largest gathering of land trusts, Bowman made a passionate plea for safeguarding biodiversity for the future. The Resilient and Connected Network is an important tool for that urgent task.

“This map provides a new way to look at the landscape for purposes of prioritizing lands for the conservation of biodiversity,” Bowman said. “I’ve watched this work take shape over the last decade, and I truly believe it marks a paradigm shift in how we think about large landscape conservation.”
